## Solution 1:

See R code  $sol\_mlr\_decision\_boundaries.R$ 

## Exercise 2:

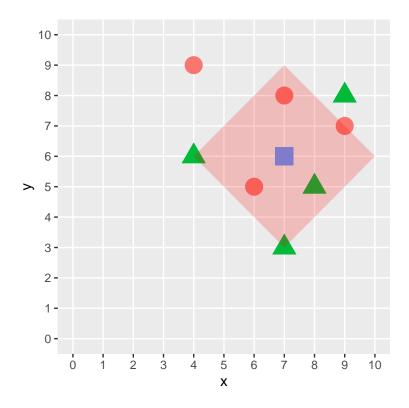

a) k = 3

2 circles and 1 triangle, so our point is also a circle

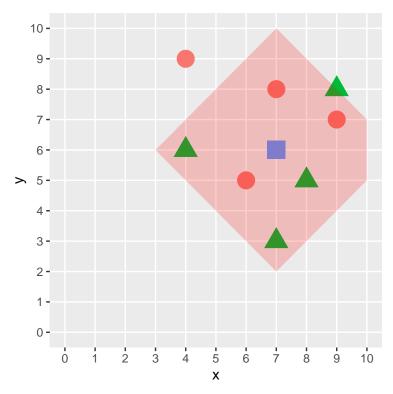

b) k = 5

3 circles and 3 triangles, we have to specify beforehand what to do in case of a tie

c) k = 7

3 circles and 4 triangles, so our point is also a triangle

## Solution 3:

a) When using the naive Bayes classifier, the features  $x := (x_{\text{Color}}, x_{\text{Form}}, x_{\text{Origin}})$  given the category  $y \in \{\text{yes}, \text{no}\}$ 

are assumed to be conditionally independent of each other, s.t.

$$p((x_{\text{Color}}, x_{\text{Form}}, x_{\text{Origin}})|y=k) = p(x_{\text{Color}}|y=k) \cdot p(x_{\text{Form}}|y=k) \cdot p(x_{\text{Origin}}|y=k).$$

For the posterior probabilities  $\pi_k(x)$  it holds that

$$\pi_k(x) \propto \underbrace{\pi_k \cdot p(x_{\text{Color}}|y=k) \cdot p(x_{\text{Form}}|y=k) \cdot p(x_{\text{Origin}}|y=k)}_{=:\alpha_k(x)}$$

$$\iff \exists c \in \mathbb{R} : \pi_k(x) = c \cdot \alpha_k(x),$$

where  $\pi_k$  is the prior probability of class k. From this and since the posterior probabilities need to sum up to 1, it holds that

$$1 = c \cdot \alpha_{\text{yes}}(x) + c \cdot \alpha_{\text{no}}(x)$$
$$\iff c = \frac{1}{\alpha_{\text{yes}}(x) + \alpha_{\text{no}}(x)}.$$

This means in order to compute  $\pi_{\text{yes}}(x)$  the scores  $\alpha_{\text{yes}}(x)$  and  $\alpha_{\text{no}}(x)$  are needed.

Now we want to compute for a new fruit the posterior probability  $\hat{\pi}_{yes}((yellow, round, imported))$ .

Note that we do not know the *true* prior probability and the *true* conditional densities. Here -since the target and the features are categorical- we can estimate them with the relative frequencies encountered in the data, s.t.

$$\begin{split} \hat{\alpha}_{\text{yes}}(x) &= \hat{\pi}_{yes} \cdot \hat{p}(\text{yellow}|y = \text{yes}) \cdot \hat{p}(\text{round}|y = \text{yes}) \cdot \hat{p}(\text{imported}|y = \text{yes}) \\ &= \hat{\mathbb{P}}(y = \text{yes}) \cdot \hat{\mathbb{P}}(x_{\text{Color}} = \text{yellow}|y = \text{yes}) \cdot \hat{\mathbb{P}}(x_{\text{Form}} = \text{round}|y = \text{yes}) \cdot \hat{\mathbb{P}}(x_{\text{Origin}} = \text{imported}|y = \text{yes}) \\ &= \frac{3}{8} \cdot \frac{1}{3} \cdot \frac{1}{3} \cdot 1 = \frac{1}{24} \approx 0.042, \\ \hat{\alpha}_{\text{no}}(x) &= \hat{\pi}_{no} \cdot \hat{p}(\text{yellow}|y = \text{no}) \cdot \hat{p}(\text{round}|y = \text{no}) \cdot \hat{p}(\text{imported}|y = \text{no}) \\ &= \hat{\mathbb{P}}(y = \text{no}) \cdot \hat{\mathbb{P}}(x_{\text{Color}} = \text{yellow}|y = \text{no}) \cdot \hat{\mathbb{P}}(x_{\text{Form}} = \text{round}|y = \text{no}) \cdot \hat{\mathbb{P}}(x_{\text{Origin}} = \text{imported}|y = \text{no}) \\ &= \frac{5}{8} \cdot \frac{2}{5} \cdot \frac{3}{5} \cdot \frac{2}{5} = \frac{3}{50} = 0.06. \end{split}$$

At this stage we can already see that the predicted label is "no", since  $\hat{\alpha}_{\text{no}}(x) = 0.06 > \frac{1}{24} = \hat{\alpha}_{\text{yes}}(x)$ . With this we can calculate the posterior probability

$$\hat{\pi}_{\text{yes}}(x) = \frac{\hat{\alpha}_{\text{yes}}(x)}{\hat{\alpha}_{\text{ves}}(x) + \hat{\alpha}_{\text{no}}(x)} \approx 0.41.$$

Corresponding R-Code:

```
id = "banana",
backend = df_banana,
target = "Banana"
)

nb_learner$train(banana_task, row_ids=1:8)

nb_learner$predict(banana_task, row_ids = 9)

## <PredictionClassif> for 1 observations:
## row_id truth response prob.no prob.yes
## 9 <NA> no 0.5901639 0.4098361
```

b) For the distribution of a numerical feature given the the category we need to specify a probability distribution with continuous support. For example, for the information  $x_{\rm Length}$  we could assume that  $p(x_{\rm Length}|y={\rm yes}) \sim \mathcal{N}(\mu_{\rm yes},\sigma_{\rm yes}^2)$  and  $p(x_{\rm Length}|y={\rm no}) \sim \mathcal{N}(\mu_{\rm no},\sigma_{\rm no}^2)$ . (To estimate these normal distributions one would need to estimate their parameters  $\mu_{\rm yes},\mu_{\rm no},\sigma_{\rm yes}^2,\sigma_{\rm no}^2$  on the data respectively)
